Technology Transfer in Agriculture: Social and Economic Aspects

by Dr Shamsul Alam Mohan

TECHNOLOGY is means to help production activities, augment outputs and make possible management of resources and products. Some technologies are in vogue over a longer period of time while some are changing or replaced wholly or partially by improved versions towards better use of resources or outputs. Technology is a dynamic concept thriving with betterment of technique(s) (technique is a single production method), and embodies simple technique to composite ones. Technological change simply refers to advances in scientific knowledge.

Access to and control of technologies needs investment by the producer. Decision to invest requires desire to risk taking, ability and technical know-how. Because of lack of fund, general inertia of habit nation with the existing techniques of production, farmers producers usually are not inclined to quick change in terms of adopting new technologies. Therefore, technology transfer and adoption in the farming practice encounter formidable problems in the developing countries.

Agricultural sector is yet the mainstay of Bangladesh economy. So, technological transformation of the agricultural sector is a necessary pre-requisite for modernization of the sector to support sustained and increased production. But there is a general lag in adoption of improved technologies owing to lack of balanced flow of information, lack of complementary inputs/resources and lower level of formal education to perceive the potentiality of change by the decision making farmers.

Agricultural Technology
Agricultural technologies can be grouped into: "Indigenous technologies and *modern technologies. Indigenous technologies have been or are generated at farm level and by farmers. In the farming community there are innovative farmers who develop or modify indigenous technologies at their own and adapt in farm practices. Modern technologies have been developed largely by improving/refining the indigenous and often imported technologies or varieties by the national research institutes. In Bangladesh, the extension organizations and NGOs are devoted more to technology transfer process than to technology generation. Yield growth has been slower in Bangladesh than in her neighbouring countries indicating lower level of technological adoption and diffusion in farming practices.

Problems of Innovation
Innovation (first practical use of a new, more productive technique) or appropriate technologies require substantial funding for research. Agricultural research institutes are primarily

entrusted with the generation/innovation of appropriate technologies in the country. On limited scale, Agricultural Universities are also creating and generating agricultural technologies. A few large NGOs are also involved in technology development and use advance technologies for increasing income for the organizations and farmers. But technological innovation faces multi-dimensional problems which can be summed up as the following:

- Inadequate funding for building research institutes.
- Shortages of skilled manpower in the existing research institutes.
- Management of the research institutes are beset with the problems of inadequate funding, lack of accountability and to an extent, visions.
- Weak linkages of the research institute with the extension services and NGOs.
- Often research priorities are not demand-driven of the farming communities.
- Lack of coordination among the research divisions/departments within the institutes.
- Lack of coordination among the research institutes which result in duplication of work and wastage of limited resources.
- Over dependence on donor assistance for research funding. Continuation of research efforts get blocked after withdrawal of donor support.
- Lack of effective people's representation (private sector) in the management of public research institutes and as a result farmers' stake is often ignored.
- Lack of cooperation/integration between national, regional and international research institutes.
- In the liberalized economic system, national institutes are failing to cope up and advance as required in encountering the available cheap technologies penetrating the markets.
- The emerging issue now-a-days is the penetration of global corporations with biological innovation (hybrid seeds) exerting their market power to drive out or overwhelm achievements/findings of the local institutes. This may even cause long-term damage of the production potentiality of the resources.

Problem of Adoption
Research institutions lack built-in mechanisms to get feedbacks from farmers and technology users.
Poor and weak linkages among the research institutes, Universities and NGOs.
Important post-harvest/processing technologies (process innovations) are lacking

to preserve farm produces for a longer period of time to market evenly throughout the year.
Absentee land ownership is on the increase and their lands are mostly under sharecropping or often remain fallow. Both absentee landlords and sharecropping land tenants are less interested in change towards modernizations. Sharecroppers may be less efficient and less open to innovation.

Social
Widespread extortion, collection of tolls, deteriorating law-and-order situation, lack of inspection of goods/commodities/tools/machinery create conditions for market failures which act as disincentives towards adopting new invention(s) for further improvement/augmentation of production and movement of marketables.

Scattered and smallness of holdings act as disincentive for adoption of mechanization and use of mechanical technologies
Technology adopted by few farms, while majority does not adopt, creates problem and lack

variation. Complementary relationship in using modern factor inputs (seeds, fertilizer, irrigation, pesticides, etc) contributes to the probability of increased risk situation in terms of use and availability of all or any of the inputs in time. Farmers especially small and marginal ones are risk averse and therefore are skeptical of immediate switchover to new innovation.

Also, for many other reasons (variations in resource possessions and access to delivery systems and imperfect markets for inputs and outputs etc), technical change occurs differentially between farm households or farm communities in location and another. All modern factor inputs pass through markets (not farm supplied) and need cash capital to buy which most of the small and medium farmers often cannot readily afford even if they wish to adopt. Therefore, provision of formal farm credit support is an essential ingredient of technological diffusion in the small

holder farming context.
Lack of information of new innovations and mature technologies in-time at the farmers level inhibit large scale adoptions.

Adoption and Transfer: What is to be Done?
Research and Extension Linkage: Transfer of technologies essentially requires closer liaison of the research institutes, Universities and the field extension services. New Agricultural Extension Policy (NAEP 1996) has emphasized coordination of extension representatives from the government, non-government organization and representatives from research institutes at the national level through working of National Technical Co-ordination Committee (NTCC) of the Department of Agricultural Extension. Representatives also should be taken from the research departments of the Agricultural Universities and from the NGOs involved in poverty alleviation programmes. This should also be true in forming Agricultural Technical Committees (each covering a number of districts in each agroecological region) of the Extension Department. As an apex institution of the NARS (National Agricultural Research System), BARC should be entrusted with the task of assessment of availability, requirement,

evaluation of devising technologies and means of quick transfer of technologies and information.
Database and Information System: Information about input (purchased), output prices, marketing opportunities, changing aggregate demand and supply, every day and weekly weather forecasts etc play important role in farm production decisions. There is a need for central database at the control of Department of Agricultural Extension bearing the responsibility of dissemination of information through various media to the public. Department of Agricultural Extension can take help of the GIS support system (at BARC) for data bases on socio economic information, soil characteristics and for other agro-climatic information according to agroecological regions. How knowledge about product prices and their marketing information influence farmers' decision about adoption of improved technologies need to be investigated (by socioeconomic

research). Information about inputs (seeds, irrigation water, fertilizer, machine power etc) and their availability is crucially important for adopting various technologies and enhancing agricultural production.

Communication: The most critical obstacle to succeed in the generation and adoption of new technologies for small-scale producers is the absence of communication and co-operation between the various groups and types of people whose contributions are essential: farmers, scientists, policy makers, extensionist, and others in the private sector. Nowadays, radio and television transmission has a direct bearing on the farmers. These media can be tapped efficiently in spreading information (visual demonstration) on mature technologies particularly of yield-increasing types which have tremendous market demand owing to land-scarcity constraints for pursuing agricultural activities. Bulletins and booklets on specific technologies/methods of production in Bangladesh could be very useful. Farmers are eager to produce as much as possible on a meagre land resource.

Farm and Field Demonstrations/Trials: Discipline based technology research may prove excellent on station and even in the trial of farmers' field, but

low quality of straw as a feed for livestock herd).
Design of Technologies: Agricultural productions are seasonal and glut the markets during the harvest seasons and prices plunge rapidly at the throw away level for which farmers often fail to achieve economic return or surplus that could be recycled for further investments. Appropriate post-harvest technologies improving preservation methods can save farmers from the seasonal low product prices trap. Industrial policy needs to be tilted towards agro processing labour intensive industries as that can increase demand for agricultural products through multifarious mode of uses and increase of shelf-life. Import policy must fulfill this technological change requirement. In designing appropriate technologies and in innovation efforts interest of the different size groups of farms and their requirements have to be looked into.
Market Structure Needs to be Competitive: Preponderance of subsistence motive in farming practices make farmers rigid, risk averse and less thriving. So majority remain non-adopters in case of many technologies not by choice, but by force of circumstance. Farming for markets that is not purely commercial line has been emerging very even in the recently enshrined market economy policies (except a few cash crops like cotton and tobacco; jute is a well known cash crop but now-a-days its prime consideration for cultivation is jute-sticks and partly rotational obligation). For ensuring profitability for the farm products, measures should be taken to make markets competitive as farmers can get more share of (investor) prices paid prices. If input and product markets become purely competitive, many of the social and institutional problems would relax gradually and exploitations by a few middlemen would go away.
The author, an agricultural economist, is Professor, Bangladesh Agricultural University, Mymensingh.

relevant costs and benefits must be known beforehand to quicken the transfer process of any technology. It is obvious and essential that rigorous prior economic appraisals must be conducted before releasing any technology or innovation which is usually not done or inadequately performed. If at all, for doing prior and post economic evaluations and assessing market potentials of any new technology, national research institutes (concerned with agricultural technologies) must have viable Agricultural Economics Divisions, which surprisingly, some of the important national research institutes like Bangladesh Jute Research Institute, Bangladesh Fisheries Research Institute, Bangladesh Institute of Nuclear Agriculture are currently lacking.
Involvement of Public and Private Sectors: There has been a tremendous boom in acquiring high-tech satellite telecommunications and uses of optic fibers in cable and cellular communication.

Research institutes lack built-in mechanisms to get feedbacks from farmers and technology users.
Poor and weak linkages among the research institutes, Universities and NGOs.
Important post-harvest/processing technologies (process innovations) are lacking

Important post-harvest/processing technologies (process innovations) are lacking

to preserve farm produces for a longer period of time to market evenly throughout the year.
Absentee land ownership is on the increase and their lands are mostly under sharecropping or often remain fallow. Both absentee landlords and sharecropping land tenants are less interested in change towards modernizations. Sharecroppers may be less efficient and less open to innovation.

Social
Widespread extortion, collection of tolls, deteriorating law-and-order situation, lack of inspection of goods/commodities/tools/machinery create conditions for market failures which act as disincentives towards adopting new invention(s) for further improvement/augmentation of production and movement of marketables.

Scattered and smallness of holdings act as disincentive for adoption of mechanization and use of mechanical technologies
Technology adopted by few farms, while majority does not adopt, creates problem and lack

variation. Complementary relationship in using modern factor inputs (seeds, fertilizer, irrigation, pesticides, etc) contributes to the probability of increased risk situation in terms of use and availability of all or any of the inputs in time. Farmers especially small and marginal ones are risk averse and therefore are skeptical of immediate switchover to new innovation.

variation. Complementary relationship in using modern factor inputs (seeds, fertilizer, irrigation, pesticides, etc) contributes to the probability of increased risk situation in terms of use and availability of all or any of the inputs in time. Farmers especially small and marginal ones are risk averse and therefore are skeptical of immediate switchover to new innovation.

Also, for many other reasons (variations in resource possessions and access to delivery systems and imperfect markets for inputs and outputs etc), technical change occurs differentially between farm households or farm communities in location and another. All modern factor inputs pass through markets (not farm supplied) and need cash capital to buy which most of the small and medium farmers often cannot readily afford even if they wish to adopt. Therefore, provision of formal farm credit support is an essential ingredient of technological diffusion in the small

holder farming context.
Lack of information of new innovations and mature technologies in-time at the farmers level inhibit large scale adoptions.

Adoption and Transfer: What is to be Done?
Research and Extension Linkage: Transfer of technologies essentially requires closer liaison of the research institutes, Universities and the field extension services. New Agricultural Extension Policy (NAEP 1996) has emphasized coordination of extension representatives from the government, non-government organization and representatives from research institutes at the national level through working of National
